Bradford Hill criteria

Strength 強度	Effect size; the larger the association, the more likely that it is causal.
Consistency 一致性	Consistent findings observed by different persons in different places with different samples.
Specificity 特異性	The more specific an association between a factor and an effect is, the bigger the probability of a causal relationship.
Temporality 時序性	The effect has to occur after the cause
Biological gradient 生物梯度	Dose-response; greater exposure should generally lead to greater incidence of the effect.
Plausibility 合理性	A plausible mechanism between cause and effect is helpful
Coherence 連貫性	Coherence between epidemiological and laboratory findings increases the likelihood of an effect.
Experiment 實驗	possible to appeal to experimental evidence.
Analogy 類比	The use of analogies or similarities between the observed association and any other associations.
Reversibility 可逆性	If the cause is deleted then the effect should attenuate as well.

Naranjo Score

	項目	是	否	不知
Plausibility	1.此不良反應是否有研究報告確定?	+1	0	0
Temporality	2.此不良反應是否發生於服藥之後?	+2	-1	0
Reversibility	3.當停藥或使用此藥之解藥，不良反應是否減輕?	+1	0	0
Consistency	4.停藥一段時間再重新使用該品項，同樣的不良反應是否再度發生?	+2	-1	0
Specificity	5.有沒有其他原因(此藥以外)可以引起同樣之不良反應?	-1	+2	0
Experiment	6.當給予安慰劑時，此項不良反應是否會再度發生?	-1	+1	0
Strength	7.此藥物的血中濃度是否達到中毒劑量?	+1	0	0
Biological gradient	8.對此病人而言，藥物劑量與不良反應的程度是否成正向關係?	+1	0	0
Analogy	9.病人過去對同樣或類似藥物是否也產生同樣的不良反應	+1	0	0
Coherence	10.此項不良反應是否有客觀的證據?	+1	0	0

ABSTRACT

OBJECTIVE

To evaluate the association between the use of antipsychotic drugs and cholinesterase inhibitors and the risk of falls and fractures in elderly patients with major neurocognitive disorders.

DESIGN

Self-controlled case series.

SETTING

Taiwan's National Health Insurance Database.

PARTICIPANTS

15 278 adults, aged ≥65, with newly prescribed antipsychotic drugs and cholinesterase inhibitors, who had an incident fall or fracture between 2006 and 2017. Prescription records of cholinesterase inhibitors confirmed the diagnosis of major neurocognitive disorders; all use of cholinesterase inhibitors was reviewed by experts.

MAIN OUTCOME MEASURES

Conditional Poisson regression was used to derive incidence rate ratios and 95% confidence intervals for evaluating the risk of falls and fractures for different treatment periods: use of cholinesterase inhibitors alone, antipsychotic drugs alone, and a combination of cholinesterase inhibitors and antipsychotic drugs, compared with the non-treatment period in the same individual. A 14 day pretreatment period was defined before starting the study drugs because of concerns about confounding by indication.

RESULTS

The incidence of falls and fractures per 100 person years was 8.30 (95% confidence interval 8.14 to 8.46) for the non-treatment period, 52.35 (48.46 to 56.47) for the pretreatment period, and 10.55 (9.98 to 11.14), 10.34 (9.80 to 10.89), and 9.41 (8.98 to 9.86) for use of a combination of cholinesterase inhibitors and antipsychotic drugs, antipsychotic drugs alone, and cholinesterase inhibitors alone, respectively. Compared with the non-treatment period, the highest risk of falls and fractures was during the pretreatment period (adjusted incidence rate ratio 6.17, 95% confidence interval 5.69 to 6.69), followed by treatment with the combination of cholinesterase inhibitors and antipsychotic drugs (1.35, 1.26 to 1.45), antipsychotic drugs alone (1.33, 1.24 to 1.43), and cholinesterase inhibitors alone (1.17, 1.10 to 1.24).

CONCLUSIONS

The incidence of falls and fractures was high in the pretreatment period, suggesting that factors other than the study drugs, such as underlying diseases, should be taken into consideration when evaluating the association between the risk of falls and fractures and use of cholinesterase inhibitors and antipsychotic drugs. The treatment periods were also associated with a higher risk of falls and fractures compared with the non-treatment period, although the magnitude was much lower than during the pretreatment period. Strategies for prevention and close monitoring of the risk of falls are still necessary until patients regain a more stable physical and mental state.

WHAT IS ALREADY KNOWN ON THIS TOPIC

Antipsychotic drugs and cholinesterase inhibitors have been reported to increase the incidence of falls and fractures in patients with major neurocognitive disorders

Confounding by indication should be considered when evaluating the association between drugs and adverse reactions because cognitive impairment and neuropsychiatric symptoms of major neurocognitive disorders might lead to a high risk of falls and fractures

WHAT THIS STUDY ADDS

The risk of falls and fractures was highest before patients started treatment with cholinesterase inhibitors and antipsychotic drugs, implying that factors other than the use of drugs might have affected the incidence of falls and fractures

Although the high risk of falls and fractures in the pretreatment period was reduced after patients received treatment, the results indicated that patients might not have regained a stable condition of their major neurocognitive disorder

Introduction

Older adults with major neurocognitive disorders are often considered vulnerable and prone to falls and related fractures.[1] Falls and fractures are the most common causes for admission to hospital in older adults and are associated with substantial morbidity and mortality.[2] Cholinesterase inhibitors are typically used to improve cognition and might be linked to the risk of falls and fractures as a result of the syncope caused by parasympathomimetic effects.[3-5] Antipsychotic drugs are commonly prescribed to treat neuropsychiatric symptoms in patients with major neurocognitive disorders,[6] and concerns have been raised about falls and fractures.[7] Because of the potential adverse effects of antipsychotic drugs, including orthostatic hypotension, sedation, blurred vision, and extrapyramidal symptoms, the United States Food and Drug Administration has suggested that a complete assessment of the risk of falls should be undertaken before the start of treatment.[8] Beers criteria[9] and other studies[10-22] have also suggested that antipsychotic drugs might be associated with the risk of falls and fractures.

Although several studies and guidelines have suggested that cholinesterase inhibitors and antipsychotic drugs might be associated with the risk of falls and fractures, other studies reached different conclusions. Jin et al and Kim et al found no association

ABSTRACT

OBJECTIVE

To evaluate the association between recently raised anticholinergic burden and risk of acute cardiovascular events in older adults.

DESIGN

Case-case-time-control study (ie, incorporating a case crossover design and a control crossover design consisting of future cases).

SETTING

Taiwan's National Health Insurance Research Database.

PARTICIPANTS

317 446 adults aged ≥65 who were admitted to hospital because of an incident acute cardiovascular event between 2011 and 2018. Acute cardiovascular events included myocardial infarction, strokes, arrhythmias, conduction disorders, and cardiovascular death.

MAIN OUTCOME MEASURES

The anticholinergic burden was measured for each participant by adding up the anticholinergic scores for individual drugs using the Anticholinergic Cognitive Burden Scale. Scores were classified into three levels (0 points, 1-2 points, and ≥3 points). For each participant, anticholinergic burden levels during hazard periods (day −1 to −30 before the cardiovascular event) were compared with randomly selected 30 day reference periods (ie, periods between days −61 and −180). Conditional logistic regression determined odds ratios with 95% confidence intervals to evaluate the association between acute cardiovascular events and recently raised anticholinergic burden.

RESULTS

The crossover analyses included 248 579 current cases. Participants' average age on the index date was 78.4 years (standard deviation 0.01), and 53.4% were men. The most frequently prescribed drugs with anticholinergic activity were antihistamines (68.9%), gastrointestinal antispasmodics (40.9%), and diuretics (33.8%). Among patients with varying levels of anticholinergic burden in different periods, more patients carried higher levels of anticholinergic burden during hazard periods than during reference periods. For example, 17 603 current cases had 1-2 points of anticholinergic burden in the hazard period with 0 points in the reference period, while 8507 current cases had 0 points in the hazard period and 1-2 points in the reference period. In the comparison of 1-2 points versus 0 points of anticholinergic burden, the odds ratio was 1.86 (95% confidence interval 1.83 to 1.90) in the case crossover analysis and 1.35 (1.33 to 1.38) in the control crossover analysis, which yielded a case-case-time-control odds ratio of 1.38 (1.34 to 1.42). Similar results were found in the comparison of ≥3 versus 0 points (2.03, 1.98 to 2.09) and ≥3 versus 1-2 points (1.48, 1.44 to 1.52). The findings remained consistent throughout a series of sensitivity analyses (eg, cut-off points for anticholinergic burden categories were redefined and different scales were used to measure anticholinergic burden).

CONCLUSIONS

An association was found between recently raised anticholinergic burden and increased risk of acute cardiovascular events. Furthermore, a greater increase in anticholinergic burden was associated with a higher risk of acute cardiovascular events.

WHAT IS ALREADY KNOWN ON THIS TOPIC

Previous studies have reported an association between anticholinergic burden and increased cardiovascular risk, but have not considered the potential issue of protopathic bias

Research has investigated the relation between anticholinergic burden and long term cardiovascular events, but variations in anticholinergic burden over time require investigation

Studies examining the effect of a recently raised anticholinergic burden on the risk of cardiovascular events are lacking

WHAT THIS STUDY ADDS

A recently raised anticholinergic burden was associated with an increased risk of acute cardiovascular events, even after addressing the issue of protopathic bias

A dose-response relation was found between anticholinergic burden and risk of acute cardiovascular events

The findings highlight the need to consider protopathic bias when interpreting the results from observational studies

Introduction

Ageing populations present various challenges for healthcare worldwide, including increases in multimorbidity rates and subsequent polypharmacy issues. Polypharmacy has been associated with various unintended clinical consequences, with a prevalence reported to be as high as 90% in older adults.[1-3] Drugs with anticholinergic activity are among the most commonly prescribed drugs in older adults with polypharmacy.[4-6] However, for most of these drugs, anticholinergic activity is not the main intended effect and is often considered a side effect. As a result, clinicians might prescribe these drugs without

Wei-Ching Huang,[1] Avery Shuei-He Yang,[1] Daniel Hsiang-Te Tsai,[1] Shih-Chieh Shao,[1,2] Swu-Jane Lin,[3] Edward Chia-Cheng Lai[1]

- **Polypharmacy** has been associated with various unintended clinical consequences, with a prevalence reported to be as high as 90% in older adults.
- Drugs with **anticholinergic activity** are among the most commonly prescribed drugs in older adults with polypharmacy.
- Anticholinergic activity **is not the main intended effect** and is often considered a side effect. As a result, clinicians might prescribe these drugs without taking into account their anticholinergic activity.
- Anticholinergic burden refers to the **cumulative adverse effect** of several drugs with anticholinergic activity.

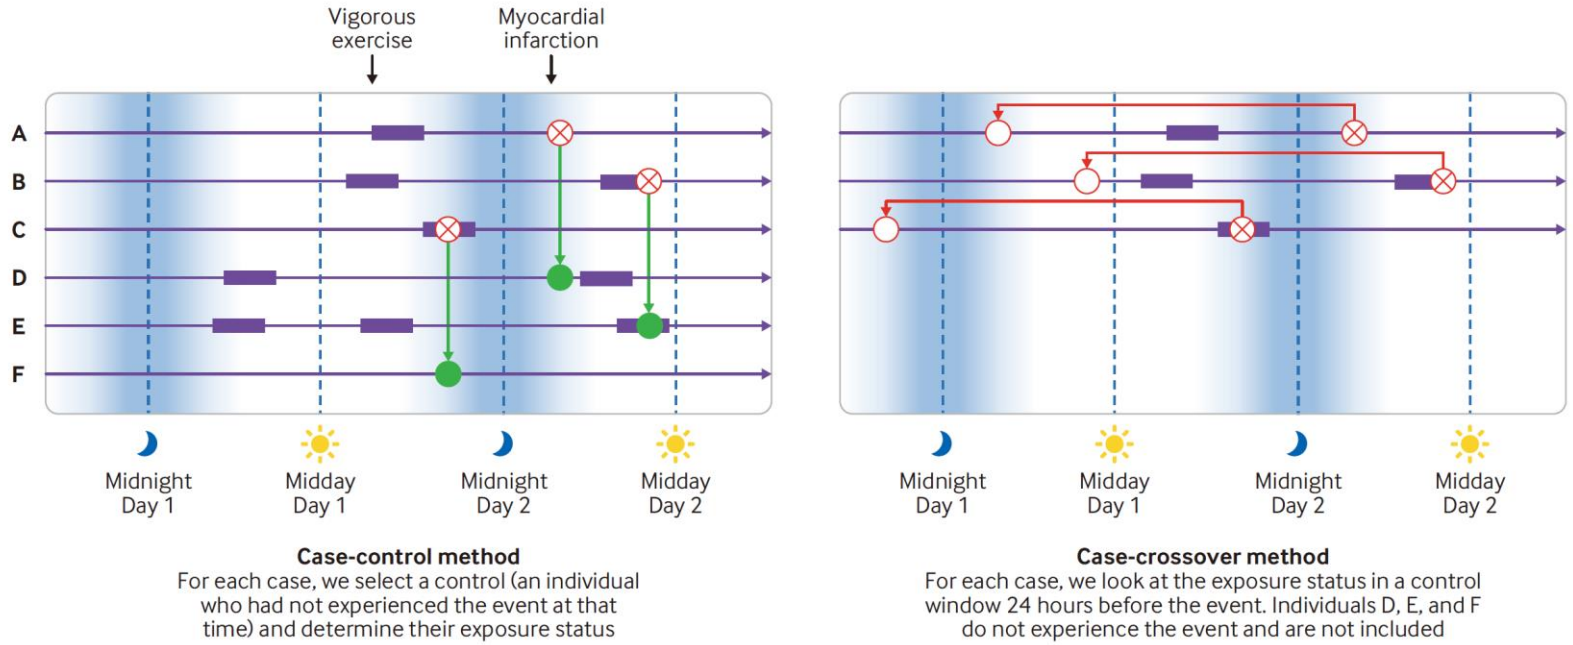
Anticholinergic burden and acute cardiovascular events

- **Biological plausibility:** anticholinergic activity has pro-arrhythmic and pro-ischaemic effects that can lead to **tachyarrhythmias** and increased oxygen requirements.
- The onset of anticholinergic effects can be **rapid** after taking a drug, which increases the likelihood of acute cardiovascular events.
- Research is needed examining the risk of **acute cardiovascular events** in the light of **recently increased** anticholinergic burden.

Introduction

The onset of anticholinergic effects can be rapid after taking a drug, which increases the likelihood of acute cardiovascular events. Research is needed examining the risk of acute cardiovascular events in the light of recently increased anticholinergic burden. Therefore, this study aimed to evaluate the association between recently raised anticholinergic burden and the risk of acute cardiovascular events. Additionally, patients receiving anticholinergic drugs might have several morbidities, leading to possible confounding by indications compared with those not receiving anticholinergic drugs.

Case-control vs Case-Crossover (CCO) (outcome anchored)



Case-control method
For each case, we select a control (an individual who had not experienced the event at that time) and determine their exposure status

Case-crossover method
For each case, we look at the exposure status in a control window 24 hours before the event. Individuals D, E, and F do not experience the event and are not included

Figure 1 | Illustrative study of the association between vigorous exercise and myocardial infarction, using case-crossover and case-control study designs. Figure shows timelines for six individuals (A to F). In a case-control study (left), individuals A, B, and C had myocardial infarctions (crossed red circles); individuals D, E, and F are controls selected at the same times (green circles); and the exposure of interest was vigorous exertion (occurring at the left edge of rectangles). A case-crossover design (right) compares the probability of exertion in the hour before myocardial infarction to the same time the previous day in the same individual (empty red circles); non-cases (individuals D, E, and F) do not contribute to the case-crossover analysis

Protopathic bias

A clinician might prescribe drugs (such as antivertigo drugs for dizziness) symptoms of cardiovascular events before a confirmed diagnosis, making challenging to infer a causal relation or even leading to reverse causality drug use and outcomes (that is, protopathic bias).

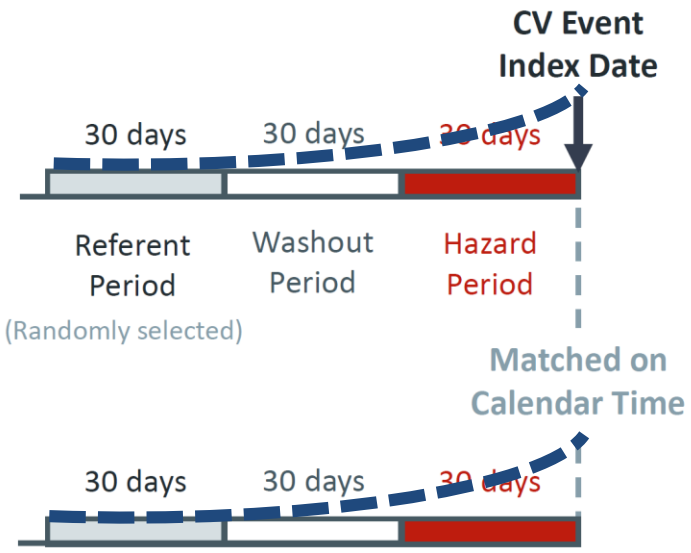
人生第一篇研究總算發表了！！！
能夠登上BMJ、達成這兩年最大的夢想
已經覺得此生無憾了🥹

從兩年前開始做研究到現在
曾經因為看見漂亮的data而一起興奮過
曾經為了難以解決的bias而苦惱卡關過
曾經在口試前三天崩潰大哭過
曾經在下班後寫manuscript 寫到睡著過
也曾經回reviewer刁鑽問題回到精神耗弱過
一路走來那些難忘的瞬間與無價的經驗
比什麼都珍貴

問題一: 群體趨勢

DRS-Matched Case-Time-Control

Control of Population Exposure Trend Bias



Case → **Case-crossover**

$OR_{case} = OR_{causal} \times OR_{time\text{-}trend}$

Control → **Control-crossover**

$OR_{control} = OR_{time\text{-}trend}$

DRS-Matched Non-Case

DRS: Disease risk score

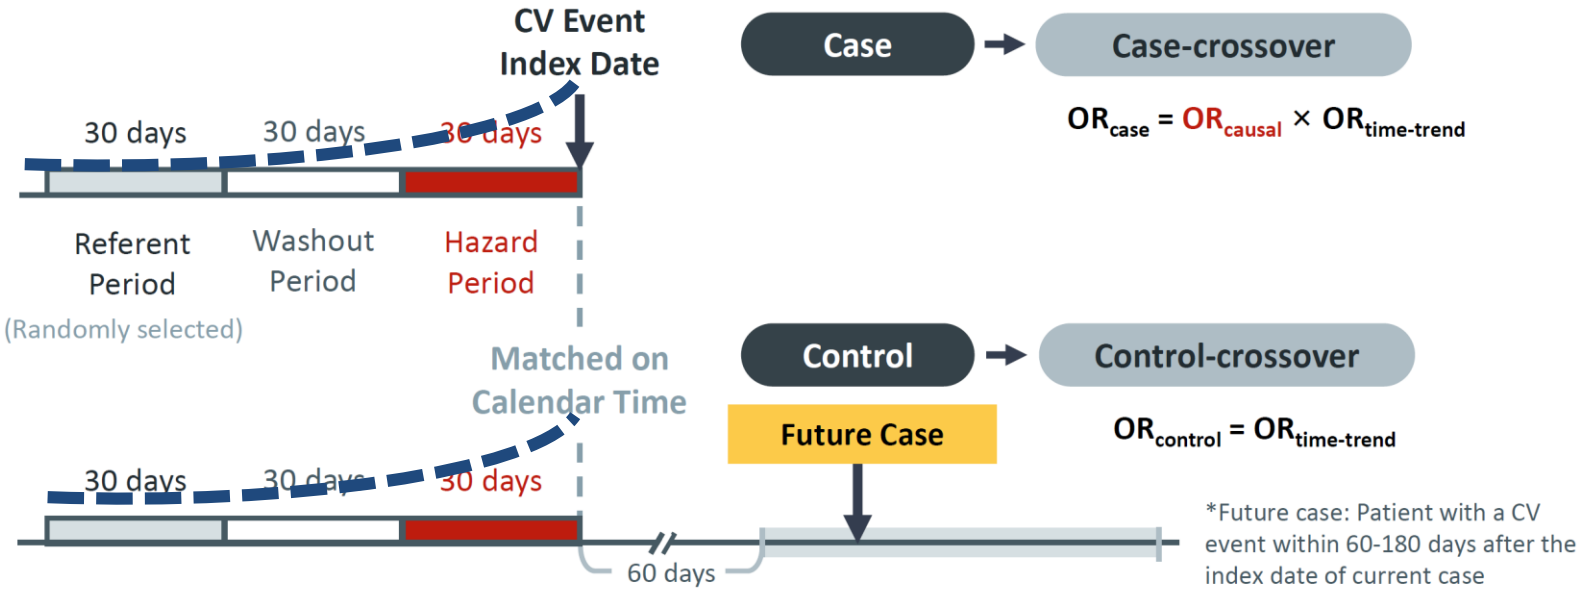
Corrected association = $OR_{case} / OR_{control} = OR_{causal}$

30

問題二: 個體趨勢

Case-Case-Time-Control

Control of Individual Exposure Trend Bias & Protopathic Bias



Corrected association = OR_{case} / $OR_{control}$ = OR_{causal}

CCTC 變成主分析

同時校正了群體與個體趨勢

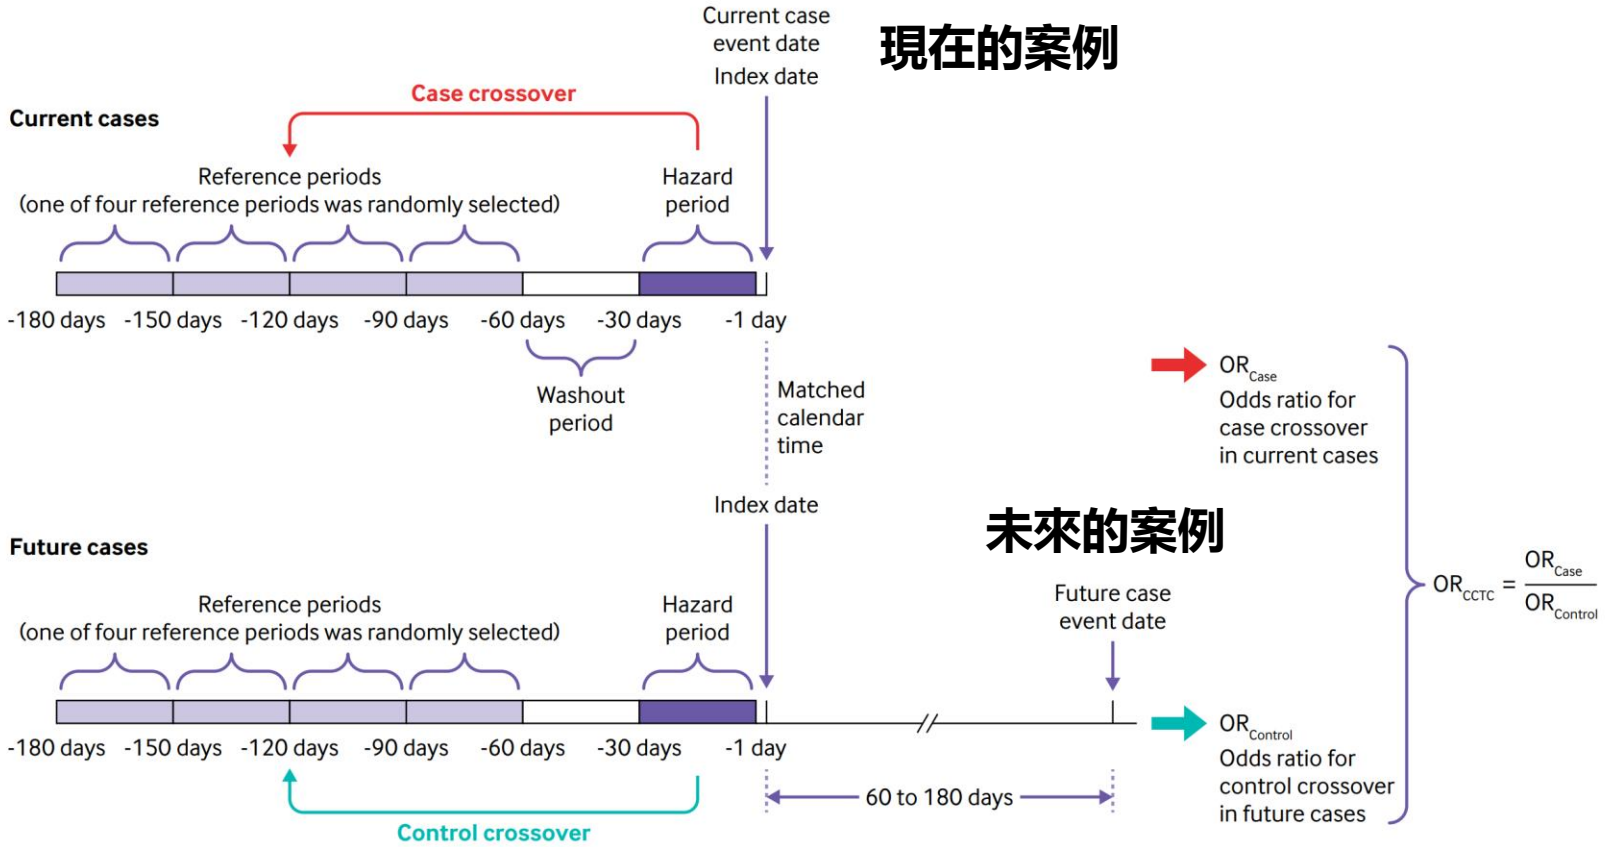


Fig 1 | Case-case-time-control (CCTC) design and details of time windows. The case-case-time-control analysis incorporated two self-controlled analyses—a case crossover analysis and a control crossover analysis consisting of future cases to address confounding by indication and potential protopathic bias, respectively

Introduction

The onset of anticholinergic effects can be rapid after taking a drug, which increases the likelihood of acute cardiovascular events. Research is needed examining the risk of acute cardiovascular events in the light of recently increased anticholinergic burden. Therefore, this study aimed to evaluate the association between recently raised anticholinergic burden and the risk of acute cardiovascular events. Additionally, patients receiving anticholinergic drugs might have several morbidities, leading to possible confounding by indications compared with those not receiving anticholinergic drugs.

Meaning of the study: possible explanations and implications

Our findings were supported by biological plausibility from existing evidence. Drugs with anticholinergic ac… …ic eff… …em plays an important role in the regulation of cardiac automaticity and contractility, and the inhibition of parasympathetic control over the cardiovascular system could increase haemodynamic lability.[46 47] This el… o… h… ir… death. Furthermore, cardiac ischaemic events can cause cardiac dysrhythmias.[15 48] Other mechanisms, such as automatic imbalance and inflammatory responses …

that the onset of anticholinergic effects can be rapid after using certain drugs.[47 53] Biological plausibility supports that recently raised anticholinergic burden could be associated with adverse events.

藥物機轉上解釋得通

有過去的文獻指出類似的結果

藥物的效果可能很快

臨床意義

Protopathic bias might arise from the increased use of drugs to manage early symptoms of cardiovascular events before diagnosis. Determining whether the anticholinergic burden caused the events or if the events led to increased drug use is challenging. To minimise possible protopathic bias, we conducted con… …l… …est… …e source of protopathic bias. The trends were then further adjusted for in the case-case-time-control analysis (supplementary information 2).[16 28 54 55] We also obtained a lower risk estimate when we manipulated the lag time to investigate the drugs in the sensitivity analyses. These findings highlighted the need to consider protopathic bias when interpreting the results from observational studies on this topic.

研究需要注意因果關係

研究意義

WHAT IS ALREADY KNOWN ON THIS TOPIC

Previous studies have reported an association between anticholinergic burden and increased cardiovascular risk, but have not considered the potential issue of protopathic bias

Research has investigated the relation between anticholinergic burden and long term cardiovascular events, but variations in anticholinergic burden over time require investigation

Studies examining the effect of a recently raised anticholinergic burden on the risk of cardiovascular events are lacking

WHAT THIS STUDY ADDS

A recently raised anticholinergic burden was associated with an increased risk of acute cardiovascular events, even after addressing the issue of protopathic bias

A dose-response relation was found between anticholinergic burden and risk of acute cardiovascular events

The findings highlight the need to consider protopathic bias when interpreting the results from observational studies

Purpose: To describe and categorize detailed components of databases in the Neurological and Mental Health Global Epidemiology Network (NeuroGEN).

Methods: An online 132-item questionnaire was sent to key researchers and data custodians of NeuroGEN in North America, Europe, Asia and Oceania. From the responses, we assessed data characteristics including population coverage, data follow-up, clinical information, validity of diagnoses, medication use and data latency. We also evaluated the possibility of conversion into a common data model (CDM) to implement a federated network approach. Moreover, we used radar charts to visualize the data capacity assessments, based on different perspectives.

Results: The results indicated that the 15 databases covered approximately 320 million individuals, included in 7 nationwide claims databases from Australia, Finland, South Korea, Taiwan and the US, 6 population-based electronic health record databases from Hong Kong, Scotland, Taiwan, the Netherlands and the UK, and 2 biomedical databases from Taiwan and the UK.

Received: 3 July 2023

Maternal diabetes and risk of attention-deficit/hyperactivity disorder in offspring in a multinational cohort of 3.6 million mother–child pairs

Previous studies report an association between maternal diabetes mellitus (MDM) and attention-deficit/hyperactivity disorder (ADHD), often overlooking unmeasured confounders such as shared genetics and environmental factors. We therefore conducted a multinational cohort study with linked mother–child pairs data in Hong Kong, New Zealand, Taiwan, Finland, Iceland, Norway and Sweden to evaluate associations between different MDM (any MDM, gestational diabetes mellitus (GDM) and pregestational diabetes mellitus (PGDM)) and ADHD using Cox proportional hazards regression. We included over 3.6 million mother–child pairs between 2001 and 2014 with follow-up until 2020. Children who were born to mothers with any type of diabetes during pregnancy had a higher risk of ADHD than unexposed children (pooled hazard ratio (HR) = 1.16, 95% confidence interval (CI) = 1.08-1.24). Higher risks of ADHD were also observed for both GDM (pooled HR = 1.10, 95% CI = 1.04-1.17) and PGDM (pooled HR = 1.39, 95% CI = 1.25-1.55). However, siblings with discordant exposure to GDM in pregnancy had similar risks of ADHD (pooled HR = 1.05, 95% CI = 0.94-1.17), suggesting potential confounding by unmeasured, shared familial factors. Our findings indicate that there is a small-to-moderate association between MDM and ADHD, whereas the association between GDM and ADHD is unlikely to be causal. This finding contrast with previous studies, which reported substantially higher risk estimates, and underscores the need to reevaluate the precise roles of hyperglycemia and genetic factors in the relationship between MDM and ADHD.

Globally, 16% of pregnant women experience hyperglycemia[1,2]. The prevalence of maternal diabetes mellitus (MDM) has increased worldwide, which is associated with the growing epidemic of obesity, advancing maternal age and improved diagnostic approaches for MDM[3,4]. There are calls for greater attention to the risks associated with diabetes in pregnancy given the increasing trend of gestational diabetes and preexisting type 2 diabetes[5]. Animal studies have demonstrated the adverse effects of hyperglycemia during pregnancy on inflammatory responses, intrauterine oxidative stress and imbalance in epigenetic mechanisms, which may contribute to poor neurodevelopment in the offspring[6,7].

Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental disorder characterized by hyperactivity, impulsivity and inattentiveness[8]. Currently, ADHD is estimated to affect 2% to 7% of children worldwide[9,10], making it one of the most common disorders among school-aged children. ADHD not only adversely impacts the

Conclusion

無法測量的干擾因子

In this large multinational cohort study, including over 3.6 million mother–child pairs and leveraging a common data model and analytic approach, we found that MDM overall, GDM and PGDM were associated with a small-to-moderate risk of ADHD in offspring. After controlling for shared familial genetic and social factors in the sibling-matched analyses, risks of ADHD did not differ between siblings with discordant exposure to GDM in pregnancy. Due to the discrepancy around the within- and between-family analyses, we speculate that the relationship between GDM exposure and ADHD may be confounded by familial factors.

Conclusion

The incidence of falls and fractures was especially high in the pretreatment period, suggesting that factors other than drugs, such as underlying diseases, should be taken into consideration when evaluating the association between the risk and the use of cholinesterase inhibitors and other drugs. The treatment periods were also associated with a higher risk of falls and fractures compared with the non-treatment period although the magnitude was much lower than during the pretreatment period. Strategies for prevention and close monitoring of the risk of falls are still necessary until there is evidence that patients have regained a more stable physical and mental state.

BMJ 2021;374:n1925

Conclusions

Our study found an association between recently raised anticholinergic burden and an increased risk of acute cardiovascular events, even after addressing the issue of protopathic bias. We also showed a dose-response relation between anticholinergic burden and the risk of acute cardiovascular events, indicating probable causation. The findings were robust throughout a series of analyses that controlled for protopathic bias and confounders unless otherwise indicated by the presence of residual confounding. Many commonly used drugs have anticholinergic effects as a secondary or primary mechanism of action, healthcare providers should increase their awareness of these effects and consider reducing unnecessary drug use.

Strengths and weaknesses of this study

This study evaluates the association between recent anticholinergic burden and risk of acute cardiovascular events. We considered variation in total anticholinergic burden in different periods befo[illegible]gs for anti[illegible]drugs wer[illegible]time-con[illegible]ding by indication owing to the self-controlled design. Our study revealed a substantial difference in the results obtained through case-case-time-control analysis compared with case-time-control analysis, highlighting the issues of protopathic bias encountered in previous studies.[12-14 16 28] However, the case-case-time-control analysis and the sensitivity analysis with different lag times addressed these concerns and revealed the robustness of the association. These findings suggest a strong association between recently raised anticholinergic burden and an increased risk of acute cardiovascular events.

Cataract Surgery and Incidence of Retinal Vascular Occlusion: Population-Based Cohort Study Using a Target Trial Emulation Framework

LI-AN WANG, AVERY SHUEI-HE YANG, YU-CHEN SU, SHENG-MIN HSU, YI-HSUN HUANG, CHAW-NING LEE, SHIH-CHIEH SHAO, SWU-JANE LIN, JIA-HORUNG HUNG, AND EDWARD CHIA-CHENG LAI

• BACKGROUND: Previous studies suggested an association between cataract surgery and retinal vascular occlusion. However, the association may be attributable to detection bias because postoperative monitoring may be more frequent for those who receive cataract surgery than for those who do not.
• DESIGN: Population-based cohort study using target trial emulation framework.
• METHODS: We included patients with cataract aged 50 years and older receiving cataract surgery or nonsurgical interventions identified from the Taiwan National Health Insurance Research Database between 2003 and 2018, matched by propensity score. The primary outcome was retinal vascular occlusion. Cox proportional hazards models were used to compare surgery and control groups. Additional analyses were restricted to patients who had undergone fundoscopic examination within 6 months prior to cataract surgery to address the issue of detection bias.
• RESULTS: We included 577,129 cataract surgery and control pairs. We found the hazard ratio (HR) for retinal vascular occlusion after cataract surgery was 1.23 (95% confidence interval (CI): 1.17-1.29), compared with the control group. Secondary outcome analyses yielded similar results for retinal artery occlusion (HR: 1.13, 95% CI: 1.02-1.26) and retinal vein occlusion (HR: 1.26, 95% CI: 1.20-1.33). However, no risk of retinal vascular occlusion was observed among patients who had received fundoscopic examinations (HR: 1.06, 95% CI: 0.98-1.15) at baseline.
• CONCLUSIONS: Our study underscored the importance of conducting complete baseline fundoscopic examinations before cataract surgery to clarify whether postoperative conditions are due to patients' underlying diseases or unintended complications of cataract surgery. INTRODUCTION

CATARACT IS THE LOSS OF LENS TRANSPARENCY DUE to opacification of the lens,[1] leading to visual impairments estimated to affect over 83 million people worldwide.[2] Cataract surgery is the most commonly performed ophthalmic procedure for visual rehabilitation, with a global estimate exceeding 20 million surgeries performed annually.[3] Modern cataract surgery is considered to be safe, and more than 84 percent of patients experience vision improvement after undergoing the surgery.[4,5] However, postoperative complications can include corneal decompensation, cystoid macular oedema, retinal detachment, full-thickness macular hole and endophthalmitis.[6] Postoperative retinal vascular occlusion has also been reported.[7-15]

Retinal vascular occlusion is a vision-threatening retinal vascular disorder. It refers to a group of retinopathies characterized by blood flow blockage in retinal arteries or veins,[16] referred to as retinal artery occlusion (RAO) and retinal vein occlusion (RVO), respectively.[17-19] The incidence of RAO is approximately 1 to 10 in 100,000, and it presents with acute painless loss of monocular vision. It is considered a form of stroke, with a similar clinical ap-

大數據分析 白內障手術 不會增加眼中風風險

2024/08/09 05:30

白內障是水晶體逐漸混濁，進而影響視力；圖為情境照，圖中人物與本文無關。（照片來源：shutterstock）

記者吳柏軒 / 台北報導

白內障為常見眼科疾病，全球約8300萬人因此視力喪失，但過去認為白內障手術恐增視網膜血管阻塞（俗稱眼中風）風險，成大團隊以大數據分析57萬多人資料，發現若術前完整眼底檢查，排除潛在或高風險眼中風病人，白內障術後發生眼中風的風險就與未接受手術的人相當。相關研究成果已刊登在頂尖眼科期刊《美國眼科學雜誌》。

成大團隊：術前完整眼底檢查 可降低風險

該研究由成大醫院眼科部醫師洪嘉鴻與成大群體健康數據中心主任賴嘉鎮共同合作。洪嘉鴻表示，白內障是水晶體逐漸混濁進而影響視力，全球約8300萬人導致因此視力喪失。依我國健保資料，台灣每年逾100萬人治療白內障，其中約12萬人接受白內障手術，該手術現今成功率達95%以上，但過去有研究指出白內障術後可能會增加眼中風發生風險，眼中風為視網膜動脈或靜脈發生阻塞，通常無明顯疼痛，延誤就診恐致視覺永久損失。

TABLE 2. Main Analysis and Secondary Outcome Analysis of This Study

	Original Cohort	
	Incidence Rate (per 100,000 Person-Year)	HR (95% CI)
Main analysis		
Surgery group	158.89	1.23 (1.17-1.29)
Control group	129.89	Reference
Secondary outcomes		
RAO		
Surgery group	35.00	1.13 (1.02-1.26)
Control group	29.20	Reference
RVO		
Surgery group	131.13	1.26 (1.20-1.33)
Control group	105.60	Reference

CI = confidence interval; HR = hazard ratio; RAO = retinal artery occlusion; RVO = retinal vein occlusion.
*We included 239,683 patients in the surgery group and 128,736 patients in the control group.

Conclusions

Cataract surgery was associated with **an increased risk** of retinal vascular occlusion; however, this association may be attributable to **detection bias**. The findings suggested **fundoscopic examination** before cataract surgery is important to confirm patients' underlying disease and to avoid unnecessary postoperative arguments about spurious associations.
